

# Unsupervised and Unstructured Machine Learning

BA820 – Mohannad Elhamod

# Intro to Clustering

# Cluster Analysis

[medium.com](https://medium.com)

# What is Cluster Analysis?

- Placing objects in groups such that:
  - the objects in a group are similar (or related) to one another.
  - They are different from (or unrelated to) the objects in other groups.
- We need a (metric/measure/objective function) to measure the (distance/similarity) of the (objects/clusters).

# Clusters are in the eye of the beholder

How many  
clusters?

Six Clusters

Two Clusters

Four Clusters

# Clusters come in all shapes and sizes

# Hierarchical Clustering

# Hierarchical Clustering

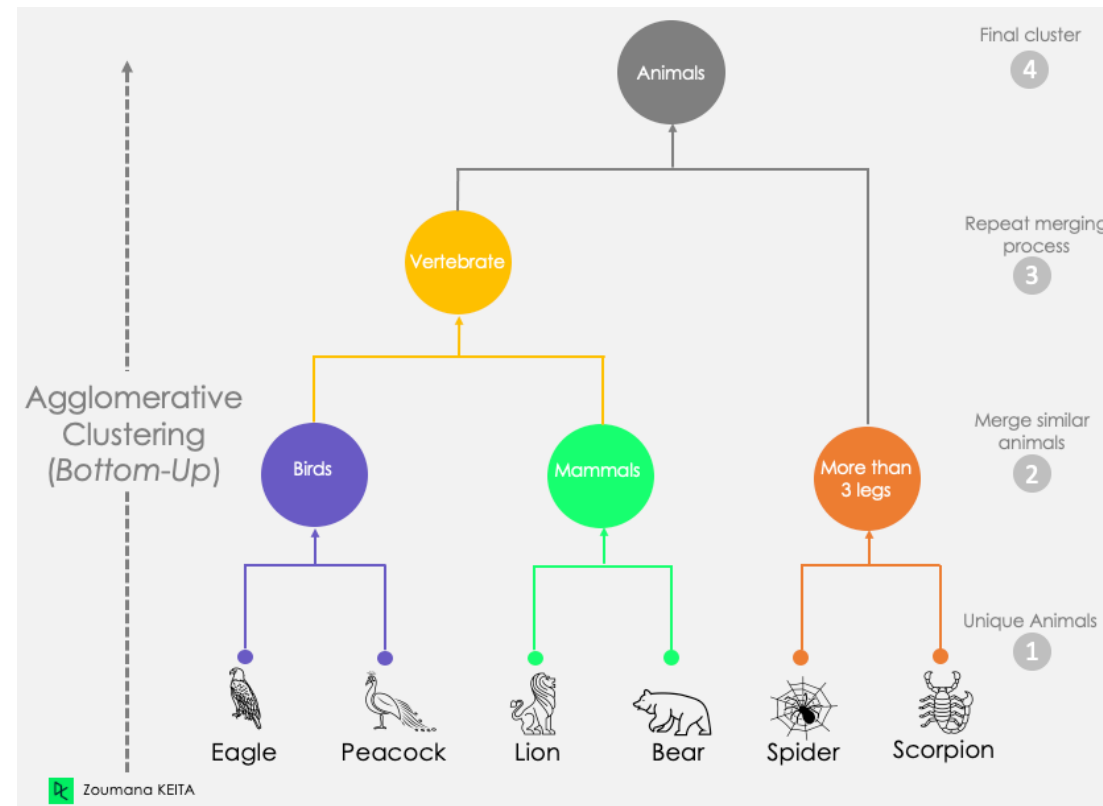

# Hierarchical Clustering

- Produces a set of nested clusters organized as a hierarchical tree
- Can be visualized as a dendrogram
  - A tree like diagram that records the sequences of merges or splits.

# Hierarchical Clustering

# Hierarchical Clustering

- **Key Idea: Successively merge closest clusters**
- Basic algorithm
  1. Compute the proximity matrix
  2. Let each data point be a cluster
  3. **Repeat**
  4. Merge the two closest clusters
  5. Update the proximity matrix
  6. **Until** only a single cluster remains
- Key operation is the computation of the proximity of two clusters
  - Different approaches to defining the distance between clusters distinguish the different algorithms

# Steps 1 and 2

- Start with clusters of individual points and a proximity matrix

|    | p1 | p2 | p3 | p4 | p5 | . . . |
|----|----|----|----|----|----|-------|
| p1 |    |    |    |    |    |       |
| p2 |    |    |    |    |    |       |
| p3 |    |    |    |    |    |       |
| p4 |    |    |    |    |    |       |
| p5 |    |    |    |    |    |       |
| .  |    |    |    |    |    |       |
| .  |    |    |    |    |    |       |
| .  |    |    |    |    |    |       |

Proximity Matrix

# Intermediate Situation

After some merging steps, we have some clusters

|    | C1 | C2 | C3 | C4 | C5 |
|----|----|----|----|----|----|
| C1 |    |    |    |    |    |
| C2 |    |    |    |    |    |
| C3 |    |    |    |    |    |
| C4 |    |    |    |    |    |
| C5 |    |    |    |    |    |

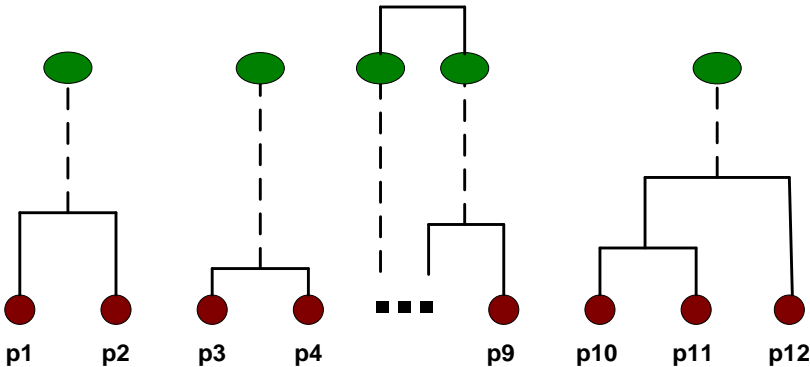

# Step 4

We want to merge the two closest clusters (C2 and C5) and update the proximity matrix.

|    | C1 | C2 | C3 | C4 | C5 |
|----|----|----|----|----|----|
| C1 |    |    |    |    |    |
| C2 |    |    |    |    |    |
| C3 |    |    |    |    |    |
| C4 |    |    |    |    |    |
| C5 |    |    |    |    |    |

Proximity Matrix

# Step 5

The question is “How do we update the proximity matrix?”

|         |   | C2<br>U<br>C5 | C3 | C4 |
|---------|---|---------------|----|----|
| C1      |   | ?             |    |    |
| C2 U C5 | ? | ?             | ?  | ?  |
| C3      |   | ?             |    |    |
| C4      |   | ?             |    |    |

Proximity Matrix

# How to Define Inter-Cluster Distance

- MIN (Single Link)
- MAX (Complete Linkage)
- Group Average
  - Ward's Method uses squared error
- Distance Between Centroids

# How to Define Inter-Cluster Similarity

- MIN (Single Link)
  - Sensitive to noise.

# How to Define Inter-Cluster Similarity

- MAX (Complete Linkage)
  - Less susceptible to noise.
  - Breaks larger clusters.

# How to Define Inter-Cluster Similarity

- Group Average
  - Middle ground between MIN and MAX.
  - If square distance is used, it is called Ward method.

$$\text{proximity}(\text{Cluster}_i, \text{Cluster}_j) = \frac{\sum_{\substack{p_i \in \text{Cluster}_i \\ p_j \in \text{Cluster}_j}} \text{proximity}(p_i, p_j)}{|\text{Cluster}_i| \times |\text{Cluster}_j|}$$

# How to Define Inter-Cluster Similarity

- Distance Between Centroids

# Hierarchical Clustering

Can handle non-elliptical shapes

**Original Points**

**Six Clusters**

# Hierarchical Clustering

- Visualization + dendograms (easy to find answer when changing number of clusters)
- Hierarchical has a high time complexity (polynomial  $O(n^3)$ ).

# Demo time!

# Partitional Clustering: K-means

# K-means Clustering

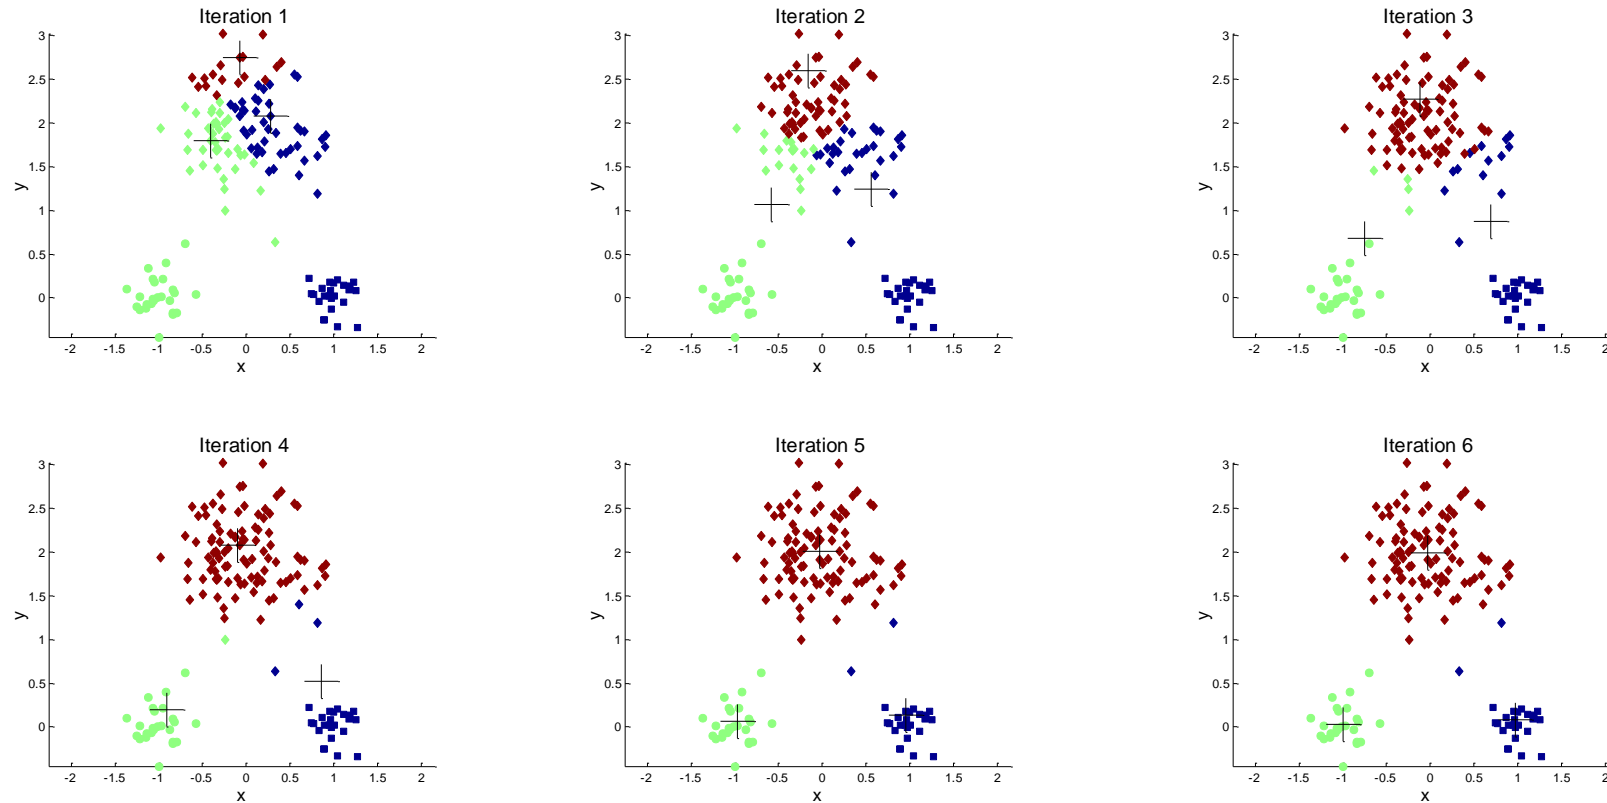

# K-means Clustering

- Number of clusters,  $K$ , must be specified in advance.
- Each cluster is associated with a *centroid* (center point).
- Each point is assigned to the cluster with the closest centroid.
- The basic algorithm is very simple

- 
- 1: Select  $K$  points as the initial centroids.
  - 2: **repeat**
  - 3:   Form  $K$  clusters by assigning all points to the closest centroid.
  - 4:   Recompute the centroid of each cluster.
  - 5: **until** The centroids don't change
-

# Example of K-means Clustering

# K-means Objective Function

- Euclidean Sum of Squared Error (SSE)
  - For each point, the error is the distance to the nearest cluster center.
  - To get SSE, we square these errors and sum them.

$$SSE = \sum_{i=1}^K \sum_{x \in C_i} dist^2(m_i, x)$$

- This is also called distortion or inertia.
- $x$  is a data point in cluster  $C_i$  and  $m_i$  is the centroid (mean) for cluster  $C_i$
- SSE improves in each iteration of K-means until it reaches a local or global minima.

# K-means Playground

- [This playground](#) helps understand the mechanism of k-means. Use it to better visualize how the distribution of data affects the clustering.

# Effect of Random Initialization

# Effect of Random Initialization

**Optimal Clustering**

**Sub-optimal Clustering**

# Limitations of K-means

- K-means has problems when clusters are of differing
  - Sizes
  - Densities
  - Non-globular shapes
- K-means is faster than hierarchical clustering.
- K-means is susceptible to suboptimal initialization.
- What do boundaries between clusters look like?
- K-means has problems when the data contains outliers.
  - One possible solution is to remove outliers before clustering

# Limitations of K-means: Differing Sizes

**Original Points**

**K-means (3 Clusters)**

# Limitations of K-means: Differing Density

# Deciding the number of clusters

**Inertia:** Sum of squared distances of samples to their respective closest cluster centers.

# Measuring Clustering Quality

# Method 1: via Labels (Cheating...)

- Testing clustering using supervised learning.
- Calculate the error between ideal labelling and assigned cluster label.

# Method 2: via Correlation

- Compute the correlation between the two matrices
- High magnitude of correlation indicates that points that belong to the same cluster are close to each other.
- Not a good measure for hierarchical clustering.
- Similarity can be calculated in many ways.
  - Here, we use  $s = \frac{Max - d}{Max}$  or  $s = \frac{1}{1+d}$  where  $Max$  is the maximum possible distance and  $d$  is the distance measure.

# Method 2: via Correlation

- Correlation of ideal similarity and proximity matrices for the K-means clustering

well-clustered data set

Corr = 0.9235

# Method 2: via Correlation

- Correlation of ideal similarity and proximity matrices for the K-means clustering

poorly-clustered data set

Corr = 0.5810
